Acknowledgments

This project was conducted with funding from the Montana Department of Fish, Wildlife and Parks and would not have been possible without the support of this agency and its staff. Staff at Wildlife Acoustics assisted with questions regarding the SM2Bat+ ultrasonic detector and SMX-U1 microphone and Kaleidoscope Pro software. Joe and Nick Szewczak provided SonoBat 4.1 software, feedback on its use, and the 2011 Humboldt State University Bat Lab's echolocation call characteristic summaries for western and eastern U.S. bats that we used to develop the call characteristic summary for Montana bats (Appendices 6 & 7 in Maxell 2015). Bowen Deng provided technical support while processing acoustic data on Montana Tech's high performance computing cluster. At the Montana Natural Heritage Program, Darlene Patzer assisted with grant administration, Scott Blum, Shannon Hilty and Alexis McEwan assisted with hand review of bat calls, and Dave Ratz assisted with downloading of weather station data from the Mesowest application programming interface.

Background

We established a long-term, ultrasonic acoustic monitoring site on USFS lands in west central Montana (Figure 1), following deployment and maintenance protocols in Maxell (2015). The detector was placed adjacent to a small lentic waterbody (Figure 2). The surrounding area was forested and topographically rugged.

Figure 1. Placement of the Scapegoat Mountain detector.

A SM2Bat+ detector with a SMX-U1 microphone was deployed on 29 May 2015 and decommissioned on 21 May 2016, for a total of 359 nights deployed. Throughout the recording period the detector functioned moderately well, recording on 211 nights or 58.8% of the time. In total this unit collected data over 13 months and did not meet our minimum of 2 years of deployment for analysis of long-term trends.

Little Brown Myotis (<i>Myotis lucifugus</i>)	3	0	13	0
Fringed Myotis (<i>Myotis thysanodes</i>)	2	0	0	0
Long-legged Myotis (<i>Myotis volans</i>)	4	0	0	0
Yuma Myotis (<i>Myotis yumanensis</i>)	0	0	1	0

Methods

Bat Detector Deployment

Across the acoustic network, detectors were placed at locations to maximize species diversity and bat activity through placement near features important for bats such as roosts, foraging areas, and waterbodies suitable for drinking. We assessed potential sites based on: (1) open water for as much of the year as possible; (2) rock outcrops and trees that might be used as roosts by bats; (3) southern solar exposure that would allow a solar panel to charge a battery even during the winter; (4) year-round accessibility; and (5) a low likelihood of vandalism. At all sites, a detector/recorder unit and microphone were deployed. The microphones at all operational sites in 2015 were upgraded to SMX-U1 microphones (Wildlife Acoustics Inc., Maynard, MA). The detector/recorder was deployed, monitored, and maintained with the equipment, supplies, settings, and protocols listed in Montana's Bat and White-Nose Syndrome Surveillance Plan and Protocols 2012- 2016 (Maxell 2015).

Many aspects of the equipment and site selections influenced the detection of a bat echolocation call and the quality of the resulting recording. These included sensitivity of the individual microphone, temperature, humidity, wind speed, and frequency, amplitude, distance, and directionality of echolocation calls emitted by bats (Parsons and Szewczak 2009, Agranat 2014). The energy of sounds spreading in all directions diminishes by one fourth for every doubling of distance because the surface area of a sphere is related to the square of its radius. Furthermore, higher frequency sounds are diminished over shorter distances because of atmospheric absorption (Parsons and Szewczak 2009, Agranat 2014). Testing of the SMX-US microphone used through June 2015 across the acoustic network indicated that bats emitting frequencies in the range of 20 kHz should be detected at distances of 24 to 33 meters from the microphone while those emitting frequencies in the range of 40 kHz should be detected at distances of 18 to 22 meters (Agranat 2014). These distances are the radii of the relevant spheres of detection around microphones when they are at full sensitivity. However, we know that sensitivity varied over time by an unknown magnitude because some precipitation and freezing events permanently reduced the sensitivity. In 2015 the microphones at active detectors were upgraded to the SMX-U1 microphone, which increased the quality of recorded calls and reduced the effect of adverse weather on microphone sensitivity over time. Due to this change in hardware, comparisons between data collected before and after June 2015 should be made with caution as the different models of microphone may affect the number of calls and species detected. Where applicable, individual reports for each unique equipment configuration were produced to minimize any interpretation errors.

Data Management & Call Analyses

Acoustic file recordings, in both original WAC and processed WAV formats, are stored in the Montana Bat Call Library which is housed on a series of 20-40 terabyte Drobo 5D storage arrays at the Montana State Library as well as a secondary offsite location to protect against catastrophic loss. Acoustic analysis results, temperature files, weather station data, and solar and lunar data were all processed and combined within SQL database tables in accordance with the general workflow pattern for data management and analysis outlined in the text and in Appendices 8-10 of Maxell (2015). Bat call sequences were analyzed with the goal of definitively identifying individual species presence by month and individual species' minimum temperatures of activity in accordance with the Echolocation Call

Characteristics of Montana Bats and Montana Bat Call Identification materials in Appendices 6 and 7 of Montana's Bat and White-Nose Syndrome Surveillance Plan and Protocols 2012- 2016 (Maxell 2015).

Weather Station Data

Weather station data were downloaded using the Mesowest application programming interface (API) as outlined in Appendix 9 of Maxell (2015). Temperature, wind speed, solar, and precipitation data were downloaded from weather stations across the regions. Distance from the detector to the station varied by site and data type. All data from weather stations were averaged by hour and associated with all call sequences recorded within this hour bin for use in our analyses.

Solar and Lunar Data

Solar and lunar data were calculated for all hours of detector deployment using the Python package *ephem* (3.7.6.0), which uses well established numeric routines to produce high precision astronomy computations (see Appendix 10 of Maxell 2015). The underlying code produces results nearly identical to data available from the U.S. Naval Observatory (Astronomical Applications Department). Precise times for sunrise, sunset, moonrise, moonset, and percent illumination at the detector were calculated based on latitude, longitude, and date. It should be noted that local topography is not incorporated into any of these calculations. Therefore, the exact timing of these events on the ground may differ slightly from those produced by this model but should typically be within a few minutes unless local terrain differs greatly from the modeled horizon (e.g. if the site is at the bottom of a canyon).

Results

Species at Site

During the deployment period, 31,208 call sequences were recorded at the Scapegoat Mountain detector. Of those, 16,851 (54.0%) were auto-identified to species and 197 were fully reviewed by hand. Of the 46 species-months with calls auto-identified to 9 different species, 14 species-months (30.4%) were confirmed by hand review for 7 species (Table 2).

Table 2. Species hand confirmed at the Scapegoat Mountain detector, by season. Species only observed previously and newly detected within the local area (50.0 km) are noted.

Species	Seasonal Presence	Acoustically Detected in Active Season	Acoustically Detected in Winter Season	Observed Previously, not Detected	New Species
Big Brown Bat (<i>Eptesicus fuscus</i>)	Confirmed Year-round	Yes			
Silver-haired Bat (<i>Lasionycteris noctivagans</i>)	Confirmed Year-round	Yes			
Hoary Bat (<i>Lasiurus cinereus</i>)	Migratory	Yes			
California Myotis (<i>Myotis californicus</i>)	Suspected Year-round	Yes			
Western Small-footed Myotis (<i>Myotis ciliolabrum</i>)	Confirmed Year-round	Yes			
Long-eared Myotis (<i>Myotis evotis</i>)	Confirmed Year-round	Yes			
Little Brown Myotis (<i>Myotis lucifugus</i>)	Confirmed Year-round	Yes			
Fringed Myotis (<i>Myotis thysanodes</i>)	Confirmed Year-round			Yes	
Long-legged Myotis (<i>Myotis volans</i>)	Confirmed Year-round			Yes	
Yuma Myotis (<i>Myotis yumanensis</i>)	Suspected Year-round			Yes	

General Patterns of Bat Activity

The patterns of activity recorded at the Scapegoat Mountain acoustic monitoring station were generally consistent with overall average bat activity patterns recorded across the regional network of acoustic detectors (Figure 3). During the active season, activity increased through the spring onto summer, peaked in July with an average of 13,934 calls recorded, and decreased in the fall. A monthly average of 2,834 calls were recorded between April and October. Activity during the winter was limited, with an average of 17 calls per month between November and March. December had the least activity, with an average of 6 calls recorded.

Figure 3. Total monthly bat passes recorded at the Scapegoat Mountain acoustic monitoring station. Months marked with an asterisk should be interpreted with caution as those data may not represent valid trend due to data collection for only part of that month, equipment malfunction or other issues.

Timing of Bat Activity

During the active season (April to October), some level of bat activity was evident throughout most of the nighttime hours. Activity often peaked immediately after sunset or close to sunrise. However, the pattern of activity varied across this period (Figure 4), likely in response to seasonal changes in the length of each night, prey availability, and physiological needs of the animals. Over the winter, the pattern of activity was less clearly tied to sunrise and sunset in most cases.

Figure 4. Average nightly activity of bats recorded at the Scapegoat Mountain acoustic monitoring station across the active season.

Temperature and Bat Activity

Throughout the study, average bat pass temperatures were generally higher than or equal to ambient nighttime background temperatures recorded at the detector (Figure 5). Bat calls were recorded at temperatures ranging from 1.1 to 22.6°C during the active season and 1.7 to 7.7°C during the winter season. Similarly, the distribution of temperatures recorded at the *WODM8* station, located 12.3 kilometers to the north-northeast of the detector, that were associated with bat passes was significantly higher than the distribution of background temperatures (Figure 6). Thus, bats consistently restricted their activity to warmer time periods from the range of background temperatures available.

Figure 5. Average bat pass temperatures (red line) and average background temperatures (black line) across the year at the Scapegoat Mountain detector.

Figure 6. A comparison of average temperatures during bat passes (red) and average hourly background temperatures (blue) recorded at the *WODM8* station, located 12.3 km to the north-northeast of the detector. Where the bars showing passes exceed hours, bat activity is higher than expected for this temperature bin.

Wind Speed and Bat Activity

Bat activity patterns in relation to wind speed recorded at the *BEFM8* station, located 18.3 km to the north-northwest of the detector, indicate that 95% of activity was at windspeeds of 2.7 meters/second and below (Figure 7). Furthermore, bats were more active than expected at windspeeds of less than 2 meters/second (Figure 8). Due to the distance between the detector and the weather station and low bat activity in winter, the patterns shown should be interpreted cautiously (e.g. wind speed at the detector may not correlate with the measured wind speed).

Figure 7. The cumulative sum of wind speeds recorded at the BEFM8 station during bat passes. The speed at which 95% of all activity occurs at or below is highlighted in red.

Figure 8. A comparison of background windspeeds recorded at the BEFM8 station (blue) and those recorded during bat passes (red). Where the bars showing passes exceed hours, bat activity is higher than expected for this wind speed bin.

Barometric Pressure and Bat Activity

Nearly 42.6% of bat activity was associated with little to no change (-0.5 to +0.5 millibars) in hourly barometric pressure recorded at the *C1904* station, located 44.7 km to the south-southeast of the detector (Figure 9). Bat activity was approximately equal to the availability of pressure change classes in the active season. During winter, bat activity was greater than would be expected in the positive pressure change classes up to 4 millibars of change per hour in the winter season, which differs from most stations across the network. However, bat activity in the winter season is low and patterns shown may not be biologically significant.

Figure 9. Hourly changes in background barometric pressure at the C1904 station (blue) compared to changes in pressure when bat passes were recorded (red) at the Scapegoat Mountain detector. Where the bars showing passes exceed hours, bat activity is higher than expected for this pressure change bin.

Precipitation and Bat Activity

At the Scapegoat Mountain detector, bats were notably less active than expected during precipitation events (Figure 10). As precipitation events are often associated with decreased temperatures and increased wind speeds, this result is not surprising and is similar to behavior observed during mist netting. Although this pattern is in line with expectations, it should be noted that: (1) nighttime precipitation events are infrequent with only precipitation documented during only 5.0% of nighttime hours; (2) the *BEFM8* weather station is approximately 18.3 kilometers away and may not accurately represent precipitation at the bat detector, and (3) precipitation was coded in hourly bins while bats are capable of flight within minutes after the passage of a storm front.

Figure 10. A comparison of hours with and without precipitation for bat passes (red) and all nighttime hours (blue) during the active season as recorded at the BEFM8 station, located 18.3 km to the north-northwest of the detector. Where the bars showing passes exceed hours, bat activity is higher than expected for this precipitation bin.

Moonlight & Bat Activity

At the detector site, bats were generally more active than expected during bright periods such as the full moon when the moon is predicted to be above the horizon (Figure 11). Generally, bats are less active during bright times, and at most sites across the network animals appear to be selecting for dark periods. The difference in behavior at this site may be due to the surrounding topography creating “light refugia” or areas that are relatively dark and provide animals the opportunity to forage in preferred environments.

Figure 11. Percent of bat passes (red) and background hours (blue) at various moon illumination categories (0% = no illumination and 100% = full moon) and with the moon above and below the horizon. Where the bars showing passes exceed hours, bat activity is higher than expected for this moon horizon/illumination bin.

Species Activity Patterns

Identification of individual species activity patterns was hindered by relatively low and potentially inconsistent rates of auto-identification of call sequences to species (Table 4 in Maxell 2015). Only Little Brown Myotis, Long-eared Myotis, Western Small-footed Myotis, Silver-haired Bat, Big Brown Bat, and Hoary Bat had relatively high rates of confirmation of monthly presence, enough calls auto-identified to examine trends, and >50 percent correct auto-identification rates of call sequences of known species identity in the Montana Bat Call Library (Table 3). For those 6 species at this site with high auto-identification confirmation, potential patterns of documented activity are shown in Figure 12. However, activity patterns for these species from auto-identified call sequences should still be regarded as speculative due to a variety of issues that might cause auto-identifications to be inaccurate and/or inconsistent (Maxell 2015).

Table 3. The number of months each bat species was confirmed by hand analysis of calls identified by automated software, the number of months reviewed, and the respective successful classification rate; only active season data are shown.

Species	Months Confirmed	Months Reviewed	Auto-Identification Success Rate
Big Brown Bat (<i>Eptesicus fuscus</i>)	1	6	16.7%
Silver-haired Bat (<i>Lasionycteris noctivagans</i>)	3	6	50.0%
Hoary Bat (<i>Lasiurus cinereus</i>)	3	4	75.0%
California Myotis (<i>Myotis californicus</i>)	1	2	50.0%
Western Small-footed Myotis (<i>Myotis ciliolabrum</i>)	3	6	50.0%
Long-eared Myotis (<i>Myotis evotis</i>)	2	4	50.0%
Little Brown Myotis (<i>Myotis lucifugus</i>)	1	5	20.0%
Yuma Myotis (<i>Myotis yumanensis</i>)	0	3	0.0%

Figure 12. Bat passes through the deployment period identified to species using SonoBat 4.1. Note that these species identification are only suggestions and should only be used to assess general trends for species for which the classifier works well.

Discussion

At this detector we confirmed the presence of 7 of 10 species previously documented in the area (Table 2). Of the confirmed species we had 3 species of State Conservation Concern (SOC) and 2 species of Potential Conservation Concern (PSOC). No confirmed species are currently listed as threatened or endangered by the U. S. Fish and Wildlife Service (USFWS). The state and federal conservation or regulatory status for observed species are listed in Table 4.

Species presence and activity metrics recorded at these sites will serve as robust baseline that can be used to assess the status of populations at sites into the future. This is particularly important due to the imminent threats to bat species posed by White-Nose Syndrome (WNS) caused by the pathogenic fungus *Pseudogymnoascus destructans* (*Pd*) and wind energy development. During this deployment, 6 of 13 months recorded met our standards for quality. As such, our assessment is that additional survey of this site may be warranted to reliably document bat activity patterns and species presence.

Listed Species Conservation

In Montana, the Northern Myotis (*Myotis septentrionalis*) is the only bat species listed by the USFWS as threatened or endangered. The USFWS has designated 9 counties along Montana's eastern border and North and South Dakota as within the range of this species, and the species has been confirmed as present within three Montana counties (MTNHP 2020). This detector was deployed at a site that was not within the range for this species.

White-nose Syndrome

To-date, the presence of *Pseudogymnoascus destructans* and associated WNS have not been detected in Montana. However, *Pd* and WNS was detected in Washington in 2015 (WDFW, USFWS, and USGS 2016) and in South Dakota and Wyoming in 2018 (NPS 2018, WYGFD 2018). These detections and the continued spread westward into the Great Plains have increased the urgency for establishing baseline metrics to assess future impacts on resident bats. Of the 10 species detected at this site, 5 have been shown to develop WNS when exposed to *Pd*. These species are Big Brown Bat, Long-eared Myotis, Little Brown Myotis, Long-legged Myotis, and Yuma Myotis (Table 4). Additionally, Silver-haired Bat and Western Small-footed Myotis have been shown to carry *Pd*, but not exhibit symptoms of WNS (Bachen et al. 2018, but see [WhiteNoseSyndrome.org](https://www.whitenosesyndrome.org) for most up to date information on species susceptibility). The remaining *Myotis* species have not been shown to carry *Pd* or develop WNS. Rather than indicating immunity, the lack of detections of *Pd* positive individuals or WNS is likely a result of their western distribution that does not overlap affected areas. As many other *Myotis* species are impacted by WNS, it is probably best to consider these species as susceptible until proven otherwise.

Through the deployment of this and other detectors across the network, we now know that winter activity is normal for many resident bat species and does not necessarily indicate the presence of *Pd* in the local area. At this detector we found that winter activity was in the second quartile (25-50%) of average activity recorded across network sites. We were unable to confirm the presence of any species during the winter season at this site (Table 2).

Wind Energy Development

Tree roosting species such as the Eastern Red Bat, Hoary Bat, and Silver-haired Bat are not known to be susceptible to WNS but suffer mortality at wind farms. Of these we detected Hoary Bat and Silver-haired Bat at the detector site. Due to the presence of these species, mortality due to wind energy is a concern for this area at current and future sites. These species often fly near turbines and suffer barotrauma when near the turbine blades. Due to these species low reproductive rate and long life, unmitigated wind energy development may cause precipitous declines of these species over the next 50 years (Frick et al. 2017). Wind energy may have indirect impacts on bats using this site due to mortality during migration or decreased regional populations. If development of wind energy is considered within the local area, mitigation measures should be implemented to reduce potential impacts on resident and migratory species.

Table 4. Management considerations for species detected within 50.0 km of the Scapegoat Mountain detector. Species presence is summarized by season and include this and any previous efforts.

Species	Seasonal Presence	Detected Active Season ¹	Detected Winter Season ²	State Status (Montana)	Federal Status	White-Nose Syndrome Impacts ³	Wind Energy Impacts ⁴
Big Brown Bat (<i>Eptesicus fuscus</i>)	Confirmed Year-round	Yes				Confirmed Susceptible - Mortality Documented	Infrequent Mortality Documented
Silver-haired Bat (<i>Lasionycteris noctivagans</i>)	Confirmed Year-round	Yes		PSOC		Detected - Possibly Susceptible	Frequent Mortality Documented
Hoary Bat (<i>Lasiurus cinereus</i>)	Migratory	Yes		SOC		No impacts	Frequent Mortality Documented
California Myotis (<i>Myotis californicus</i>)	Suspected Year-round	Yes				Likely Susceptible	Infrequent Mortality Documented
Western Small-footed Myotis (<i>Myotis ciliolabrum</i>)	Confirmed Year-round	Yes				Detected - Likely Susceptible	No Mortality Documented
Long-eared Myotis (<i>Myotis evotis</i>)	Confirmed Year-round	Yes				Confirmed Susceptible - Mortality Documented	No Mortality Documented
Little Brown Myotis (<i>Myotis lucifugus</i>)	Confirmed Year-round	Yes		SOC		Confirmed Susceptible - Mortality Documented	Infrequent Mortality Documented
Fringed Myotis (<i>Myotis thysanodes</i>)	Confirmed Year-round	Yes		SOC	BLM - Sensitive	Likely Susceptible	No Mortality Documented
Long-legged Myotis (<i>Myotis volans</i>)	Confirmed Year-round	Yes				Confirmed Susceptible - Mortality Documented	Infrequent Mortality Documented
Yuma Myotis (<i>Myotis yumanensis</i>)	Suspected Year-round	Yes		PSOC		Confirmed Susceptible - Mortality Documented	No Mortality Documented

Management Recommendations

Measures of overall bat activity near the detector, hand confirmed presence of individual species by month, and hand confirmed minimum temperatures associated with bat passes of individual species are all stable metrics upon which management recommendations can be made. However, patterns of activity of individual species resulting from automated analyses should be used with a great deal of caution due to low rates of species assignment and low or uncertain rates of accuracy of those assignments. Furthermore, it should be noted that bat activity measured during this study was made by a microphone on a nine to ten-foot mast and may not have adequately sampled the activity of high flying bats such as the Hoary Bat and Silver-haired Bat, which together with the Eastern Red Bat are the three species that have suffered approximately 75% of the documented mortalities associated with wind turbines across North America (Kunz et al. 2007). Thus, the following management recommendations avoid use of activity patterns of individual species as determined by automated analyses and instead rely on results of hand confirmed analyses, general patterns of bat activity that were recorded at the study site, and results of published studies of wind turbine impacts on bat species.

General management recommendations for species observed at project sites include:

- (1) Protect potential natural roost sites by conserving large diameter trees (especially snags with loose bark), rock outcrops, cliff crevices, and caves.
- (2) Maintain accessibility for underground mine entrances that bats may be using as summer or winter roosts. Install bat friendly gates if closure is required.
- (3) When removing bat colonies from buildings or other structures follow current best practices, including waiting until the late fall and winter to seal entry points and placing bat houses to compensate for elimination of the roost.
- (4) Reduce structural complexity of vegetation (e.g., short stature grasslands) and availability of standing waters in proximity to wind turbines or other human structures that might represent a threat to bats or where bats are undesired.
- (5) In safe environments, maintain lotic or lentic waterbodies to provide habitat for foraging and drinking.
- (6) If wind turbines are installed in the region, set turbine cut-in speeds to > 6.0 m/sec between April and October – especially important in July during peak bat activity when young are newly flighted, and August, September, and October when migratory species are passing through and local bats are swarming and breeding. Feather wind turbine blades, making them parallel to wind direction, when wind speeds are < 6 m/sec to reduce risk of barotrauma during times of relatively high bat activity.
- (7) Report dead bats of any species found in the winter or spring to Montana Fish Wildlife and Parks or Montana Natural Heritage Program personnel. Animals found dead during these seasons may have contracted WNS and should be tested as part of Montana's Passive WNS surveillance protocol.
